<tbody>
<tr>
<td>Elandsfontein, South Africa</td>
<td>&gt; 600 Kyr</td>
<td>A cranial vault and mandibular fragment. The cranium has several traits typically seen in <em>H. erectus</em>, such as a supraorbital sulcus and moderately angled occipital. It shows an increased cranial capacity at 1225 cc (Archer &amp; Braun 2010; Klein et al. 2007; Rightmire 1988; Singer 1954).</td>
</tr>
<tr>
<td>Bodo d’Ar, Middle Awash, Ethiopia</td>
<td>630 Kyr (40Ar/39Ar)</td>
<td>A large partial cranium, with estimated 1250cc cranial capacity, a broken parietal and humerus. The cranium has a very broad, robust face, with an extremely broad nose (the largest of any Pleistocene hominin) with no marked lower nasal margins. It has an expanded maxilla, and an associated lack of a canine fossa, with the robust zygomatic arches arcing backwards. It has a thick, continuous supraorbital torus and pronounced flexion of the cranial base (Asfaw 1983; Clark et al. 1994; Conroy et al. 2000; Rightmire 1996; White 1986).</td>
</tr>
<tr>
<td>Broken Hill, Kabwe, Zambia</td>
<td>~ 600 ? Kyr (?Fauna)</td>
<td>Complete cranium and other fragmentary remains (a cranial fragment, a R maxilla, a fragmentary humerus, 2 pelveses, 6 femoral fragments, a fragment of tibia); the associations among the fossils, and between them and the fauna and stone tools are uncertain. The cranium (1325 cc) combines archaic <em>Homo</em> features (e.g. forward setting of the face in relation to the anterior cranial fossa, reduced cranial basal flexion, very large supraorbital tori) with derived traits (e.g. vertical nasal margin, palatal anatomy and brain size) (Trinkaus 1998, 2002; Stringer 1986; Rightmire 2002; Wells 1995).</td>
</tr>
<tr>
<td>Ndutu, Tanzania</td>
<td>500-300 Kyr ? (lithics)</td>
<td>A relatively small cranium (1100 cc), with anatomical details that differentiate it from <em>H. erectus</em> (e.g. size of the articular tubercle in the mandibular fossa, thickness of the tympanic place, small supraorbital tori, and absence of strong muscular markings (Clarke 1976, 1990; Leakey &amp; Hay 1982; Rightmire 1983).</td>
</tr>
<tr>
<td>Berg Aukas, Otavi, Namibia</td>
<td>500-200 Kyr ?</td>
<td>The proximal half of a very robust hominin femur. It has a flatter neck in antero-posterior dimensions than is typical of <em>Homo erectus</em>, while its subtrochanteric antero-posterior flattening differentiates it from modern femora; its most striking feature is the level of cortical thickness, which at mid-shaft is the greatest recorded (Grine et al. 1995; Trinkaus et al. 1999).</td>
</tr>
<tr>
<td>Lainyamok, Kenya</td>
<td>392-330 Kyr (40Ar/39Ar)</td>
<td>Teeth and a fragment of femoral shaft (Potts et al. 1988; Shipman et al. 1983)</td>
</tr>
<tr>
<td>Wadi Dagadlé, Djibouti</td>
<td>~400-250 Kyr ? (fauna, TL)</td>
<td>Partial maxilla (Bonis et al. 1984, 1988)</td>
</tr>
<tr>
<td>Garba III, Melka Kunturé, Ethiopia</td>
<td>400-250 Kyr ? (fauna, lithics)</td>
<td>Cranial fragments associated with fauna and lithics (Chavaillon et al. 1987)</td>
</tr>
<tr>
<td>Hoedjiespunt, South Africa</td>
<td>300-200 Kyr ? (TL, ISL, fauna)</td>
<td>Fragments of cranial and post-cranial bones, and teeth (Berger &amp; Parkington 1995, Stynder et al. 2001)</td>
</tr>
<tr>
<td>KNM-ER3884 Guomde, Kenya</td>
<td>270 Kyr (Y-ray spectrometry)</td>
<td>A partial cranium and femur; the occipital bone is comparatively derived, and like LH18, resembles a modern human anatomy (Bräuer et al. 1992, 1997).</td>
</tr>
<tr>
<td>Florisbad, Free State, South Africa</td>
<td>250 ± 35 Kyr (ESR)</td>
<td>A fragmentary cranium with a partial face, which has had several reconstructions. The remains show some derived features, such as a relatively broad frontal bone and a possible canine fossa, but the latter may not be homologous with the human condition (Clarke 1985, Grün et al. 1996, Kuman et al. 1999; Maddux &amp; Francisca 2009, Rightmire 1978, 2009).</td>
</tr>
<tr>
<td>Kébibat, Rabat, Morocco</td>
<td>~200-130 Kyr (U-s on shell)</td>
<td>Fragments of the cranium and mandible of a juvenile hominin, found in association with a mammalian fauna that suggests a late Middle Pleistocene age (Debénath 2000)</td>
</tr>
<tr>
<td>Ngaloba, Laetoli, Tanzania</td>
<td>200-120 Kyr ? (U-s, fauna, lithics)</td>
<td>A relatively complete cranium, in which a combination of derived and archaic features are seen (e.g. thick supraorbital tori, which are nevertheless clearly separated into medial and lateral sections, overall cranial breadth, and a curved occipital) (Day et al. 1980; Magori &amp; Day 1983; Rightmire 1988).</td>
